Summary

Powdery mildew is an important disease in commercial members of the cucumber family. The specific pathogen that infects cucurbits in California is *Podosphaera fusca* (synonyms: *P. xanthii*, *Sphaerotheca fulginea* and *S. fusca*), (Janousek et al. 2009, McGrath and Thomas 1996, Pérez-García et al. 2009). Over-wintering chasmothecia produce ascospores that then develop into colonies on leaves, leaf petioles, and stems (McGrath and Thomas 1996, Glawe 2008). Wind disperses conidia. (Blancard et al. 1994). Favorable conditions for disease epidemics include temperatures between 20-27°C and low-intensity light (McGrath and Thomas 1996). Disease outbreaks in the Central Valley of California tend to occur during late summer and autumn months, but coastal areas may be continuously threatened (Davey et al. 2008). Infections have the potential to reduce the yield and quality of fruit and can lead to early plant death (Blancard et al. 1994, McGrath and Thomas 1996).

Disease management in cucurbits usually involves foliar applications of synthetic fungicides and/or use of disease resistant cultivars (McGrath and Thomas 1996). Fungicides such as azoxystrobin, myclobutanil, quinoxyfen, trifloxystrobin, triflumizole, and micronized sulfur can be used to treat plants (Davis et al. 2008). Sulfur has the advantage of little or no risk of selecting for resistant mildew strains (Blancard et al. 1994). Previous work in our lab has shown that quinoxyfen, triflumizole, and penthiopyrad are highly effective at managing powdery mildew in disease susceptible varieties (Janousek et al. 2007, 2009).

We conducted a field trial at the UC Davis plant pathology experimental farm in Solano County, California to evaluate the effectiveness of ‘soft-chemistry’ and synthetic fungicides in managing powdery mildew on pumpkins (*Cucurbita pepo*) using the susceptible cultivar ‘Sorcerer’. We applied fungicides every 7 to 14 days for a six week period beginning Aug 22 and continuing through Oct 3. Following four or seven applications (depending on treatment) we assessed disease incidence and powdery mildew colony density on the upper and lower surfaces of leaves in each treatment.

Figure 1. a) Pumpkins in field at maturity and b) Pumpkin leaf showing powdery mildew.

Materials and Methods

Experimental design	Complete randomized block design with 4 replicates.		
Application method	Backpack sprayers		
Plot length	14 feet	Bed spacing	16 feet
No. plants/plot	Approximately 7	Plot area	112 ft ² (14 ft by 8 ft)
Plant spacing	variable	Area/4 plots	448 ft ² (=0.0103 acres)
Application period	22 Aug – 3 Oct (7 and 14 day intervals)		
Volume water applied	100 gallons/acre=1.0 gallons/acre 150 gallons/acre (=1.6 gallons per treatment) 225 gallons/acre (=2.3 gallons per treatment)		

\
